I want to get the ips in the form of: ips:xx.xx.xx.xx:xx.xx.xx.xx I want to make it in powershell, my code looks like this: \$a = [regex] '(.*)(.*)' \$matches.IsMatch(\$a) A: I would have use the following regex (it is the one you've used in your question): 'ips:([\s:]+):(.*)' (The \s+ is not necessary, but it is important to add as you need the [\s:]+ to match the last :).

You can find the start and the end in the first group. Note that the second group contains a *, which is greedy and matches everything until the last :. Matching groups in a regular expression The brackets ([]) are optional but you have to use them if you want to capture groups in a regular expression. The regex that we've just discussed only uses one group in the square brackets, but it can use multiple groups if it wants to. Let's start from the [] in the regex. This tells the regex engine that we are about to define groups of items and that we are interested in those groups in the matching process. The items are always defined with these curly brackets. The first item is a literal curly bracket { }. Inside it, we see the square brackets []. These square brackets tell us that we want to find matches within the following group. Inside the [], the first item is called the 'quantifier'. This means that you can specify a minimum or maximum value for this quantifier. In our case, we want to find a minimum of one item, hence the (.*). Thus the first group inside the square brackets. The second item inside the square brackets can be a quantifier too. In this case, it is the (.*)'. This means that we only want to find one item. So what is the difference between (.*') and (.*)? If you use (.*) you will get the contents of the first group as the matched value (because you have not put a quantifier inside the second item in the bracket []). But if you use (.*)', the result will be the contents of the first group first and then the second item in the square brackets. In the previous example,
